Chapter 1 , Section World Geography Chapter 1: Exploring Geography Section 1: The Study of Geography Section 2: Changes Within the Earth Section 3: Relative location describes the location of a place compared to other places. Formal regions are areas in which a certain characteristic is found throughout them. Functional regions consist of a central place and the surrounding places affected by it. How is absolute location described? Chapter 1 , Section 1 Want to connect to the World Geography link for this section? Landforms and other surface features make up the lithosphere. The atmosphere is the layer of air, water, and other substances above the surface. The water in lakes, rivers, and oceans, and water beneath the surface is the hydrosphere. The large landmasses in the oceans are the continents. Landforms are categorized by their differences in relief, or the differences in elevation from the highest to the lowest points. The theories of continental drift and seafloor spreading support the theory of plate tectonics, and it is thought that the force of convection drives the movement of tectonic plates. The Ring of Fire is a group of volcanoes and volcanic islands around the rim of the Pacific Ocean. Section 2 Review What term is used to describe the water on and below the surface? Chapter 1 , Section 3 Mechanical Weathering Mechanical weathering occurs when the rock is physically weakened or broken. The most common mechanical weathering occurs when water freezes in cracks in rock. Chemical Weathering Chemical weathering alters the chemical makeup of rock. Water and carbon dioxide are the most important factors. Acid rain is a type of chemical weathering caused by air pollution and water. Observing Weathering The wearing effects of weather can be seen in any old stone structure. Weathering changes natural landforms over millions of years. Moving water is the single greatest cause of erosion, especially when carrying sediment. Wind, the second major cause of erosion, can strip away exposed soil, but windblown deposits of loess, mineral-rich dust and silt, can also benefit farmers. Glaciers, huge, slow-moving sheets of ice, are also major agents of erosion, as they pick up and drag along dirt, rocks, and boulders. In places where glaciers have melted and receded, they have left behind ridgelike piles of rocks and debris called moraines. Section 3 Review Acid rain is a type of sediment. How can wind be a force of erosion? Chapter 1 , Section 3 Want to connect to the World Geography link for this section?
