Chapter 1 : MIT NSE: Faculty: Neil E. Todreas

Written by leading experts from MIT, Nuclear Systems Volume I: Thermal Hydraulic Fundamentals, Second Edition provides an in-depth introduction to nuclear power, with a focus on thermal hydraulic design and analysis of the nuclear core. A close examination of new developments in nuclear systems, this book will help readers—particularly.

Professor of Nuclear Engineering, Research Research Interests Thermal hydraulic aspects of nuclear systems performance under steady-state and accident conditions, advanced light water reactor LWR and fast reactor concepts, and safety features of operating LWRs of western design. Current Research Interests Student participation in all projects requires nuclear engineering course preparation. Innovative Water Reactor Concepts The goal of the efforts is to achieve long life core with a high degree of passive safety and greatly reduced capital cost. Means to achieve physical protection of these reactors is also of interest. The current design focus is on the offshore miles , floating housing the reactor in a cylindrical oil rig-like structure nuclear plant called the OFNP. Investigate the Long-Term Technical and Economic Viability of Existing Nuclear Plants Investigating the long-term technical and economic viability of existing nuclear plants is a national imperative for clean and secure electric power. This objective can be furthered by evaluation of the potential for aggressive power uprates for nuclear power plants as part of life extension programs for operation beyond 60 years. This research task will upgrade the integrated decision analysis methodology developed in a recently completed Ph. The analysis methodology is based upon analysis of the performance, safety, and economics associated with plant performance at the added capacity afforded by the adoption of advanced technologies. New worldwide interest in sodium cooled fast reactors increases the necessity of a sound correlation for pressure drop calculation. There are several areas in which the CT correlation can be upgraded to make its prediction capability even better. This project will enhance the formulation of CT and verify its improved prediction capability by comparison to the available published data and computational fluid dynamic results. Sodium and Gas Cooled Fast Reactor Design This work investigates design options for these fast reactors to improve their economic competitiveness while retaining safety features sufficient to meet safe performance needs. The safety structure being applied is the new US regulatory technology neutral framework which presents new criteria for evaluating innovative design features. Ice Condenser Containment The ice loading in these containments has led to a series of costly maintenance and design basis issues because of its sublimation and blockage of flow paths. The concept of replacing this ice with thin solid structure to absorb energy appears promising and merits further exploration. Thermal Analysis of Waste Fuel in Storage and Transportation Horizontal rod bundles in storage and transportation must be kept under certain maximum temperatures. Prediction methods and experimental data for such arrays exist. New input for the benchmark industry code used for these analyses have developed but need to be adjusted and validated based on comparison with existing experimental data. Thermal Hydraulic Fundamentals, 2nd ed. Updated with new information about advanced nuclear fuel designs, two-phase flow and heat transfer, and pre- and post- accident energy sources in nuclear plants.
