*The Technics SL is a high-quality, belt-driven turntable with a newly developed FG (frequency generator) servo-controlled DC motor with IC. The unit features fabulous wow, flutter and rumble rating and has low power consumption for greater efficiency.*

Contact Us Bought a Technics SL from eBay, and this is a short article on what it took to get this vintage turntable running. An old unit seemed the way to go, I expect others to realize the same. We were originally an electronics design engineer at Fairlight Instruments in the early s, refining the digital and analog electronics of their sampling music workstation, and went to Roland Corporation Japan for 15 years to be involved with things like the Roland A, A, A, VP, R-8 human drum machine and other stuff. Contact us if you might be able to use our services, be they technical or graphic design. May 18 What is a Technics SL? This belt drive, DC Servo turntable was the affordable model in the line up. I always thought it looked great. It has a massive S shaped tone arm and a rather nice cueing lever. On arrival it was found the belt was missing. A search on the web indicated it needed a 0. Dick Smith Electronics sells a pack of 11 turntable belts, and one was found to be suitable. The belt must be tight enough to not fall off the inner turntable rim, and not too tight to stretch to the drive spindle. The platter now rotated. Opening up the unit and tracing the wiring through, found that the audio cable as it passed through the grommet in the metal back panel was intermittent. The grommet makes the cable pass through a U that had caused the cable to fail over the years. Shortening the cable by 10cm and resoldering the connections inside, on the PCB the very fine wires from the tone arm connect to, fixed the problem. This PCB is under a metal shield plate held by two screws. The audio cable used is very low capacitance, from the units CD-4 compatible heritage. The whole cable could be replaced with newer higher capacitance cable and it would not cause any problems. CD-4 is long dead. We now had two working channels. The speed stability of Touching the fine speed adjustment pots would stop the platter completely. Another search on the net indicated the pots, electrolytics on the servo board and the speed select switch have caused problems for others. The 16mm 5k Linear pots, with fluted shafts where replaced from suitable units from Dick Smith Electronics R Note that the shafts need trimming so the knobs do not stick up too high. This switch has two bolts that hold it together, making the dismantling easy. It has many small parts! Be carefull not to loose any. The speed was now not adversely effected by touching the switch or speed trimmers. They did what they were supposed to do. We were making progress, but speed stability was still a problem. The speed was still randomly wrong. Electrolytics can dry out, or leak over time, so just replacing them all is cheap and easy. I used a Soldapullt and solder wick to get to the capacitor leads. Note that the leads of the caps bend flat to the PCB, so care is needed in removing them. If you apply too much heat to the PCB, you will lift tracks and need to replace the connections with wire. Modern caps are also smaller. The little PCB is mounted near the center of the turntable via two screws. There are 10 flying leads attached, but it is easy to work on the board without removing them. The Servo PCB top side of my unit is like:
