How Much Does an Elephant Weigh? There are many factors that affect the weight of an elephant. On average an adult weighs about 10, lbs. But there are various elements that can cause this figure to increase or decrease.

The African Elephants The African savanna bush elephants are the largest variants alive today. On average they weigh over 16, lbs over 8 tons. They can reach a height of over 13 ft. The largest one on record weighed over 13 tons. That is more or less 30, lbs. The longest tusks found so far measure 11 ft. The heaviest tusks weighed a combined lbs. The African type has many distinguishing characteristics over the regular elephant. Aside from size, its ears go down around the shoulder area. A fully grown male bull usually reaches a height of 13 ft around 4 m. The weight of an elephant is around 15, lbs or 7, kg for this type. Females called cows are smaller. The average height is 9 ft 3 m. Their weight average is 8, lbs or 3, kg. However females higher than 9 ft have been reported, but not yet confirmed.

Asian Elephants Asian elephants are not as large as the bush elephants. While stockier, the males max out at 10 ft. That is about the size of the female bush elephant. The Asian male typically weighs 5, lbs 2, kg. Females reach heights of 8 ft 2. **Measuring the Weight of an Elephant** Trying to determine its true weight is difficult. The measurement is done in centimeters. The girth around the heart is then multiplied by The length is multiplied by 7. The footpad is multiplied by These are added to get a weight assessment. The resulting figure is its weight in kilograms. After that, it is merely a matter of converting it into pounds or tons.

Factors that Affect Weight The estimates are based on elephants fed properly in zoos. The weight of an elephant will be influenced by their environment. Those living in the forests or fending for themselves weigh less. The abundance or lack thereof of food and water will also affect its weight. Obviously a sick elephant will lose appetite and also some pounds. These animals by the way, are always growing. Well fed babies weigh about kg and gain a kilogram a day. Their weight gain continues well into adulthood. To be more specific: That is also equal to a couple of pickup trucks. Other animals like the rhinoceros, do not come close. Learning the weight of an elephant can be a fascinating activity. As one gets to know more about the animal, the appreciation for it increases too.

September 7, 2007 EclecticGeek Natural progression after viewing fibroid pictures. With all the shapes and sizes, you can see why getting an answer to the fibroid weight question can prove difficult. Lots of thoughts about this in another post. The original fibroid weight question: So, I set out to search for an answer. From a couple of my responses: Started camping out at Google Scholar and PubMed typing in keywords to search fibroid weight, weight of fibroids, fibroid weight calculation, etc. I think part of the problem is the shape. I was running out of ideas at this point. Fortunately, a contributor provided a spark to jump start my thought processes again. From the geeky fibroid weight comment: Then I searched some clinical abstracts and I did find a couple of abstracts listing average weight in surgery comparisons! Hang with me for the last little bit. When I started reading what you said about volume, it clicked. Density is a problem but also shape. Women are getting different dimensions for the fibroids. Some get three i. More rectangular I guess? Some get only one i. For two dimensions i. Now, here is some review material, a few volume equations, and an online calculator. Did I just sound like a teacher?

It seems like a simple question. First, not everyone goes through puberty at the same time: Some kids start developing as early as age 8 and others might not develop until age 12. Second, people have different body types. Some are more muscular or shaped differently than others. People Grow and Develop Differently Not everyone grows and develops on the same schedule, but most people go through a period of faster growth during their teens. During puberty, the body begins making hormones that spark physical changes like faster muscle growth particularly in guys and spurts in height. As the amount of muscle, fat, and bone in the body changes during this time, some people might gain weight more rapidly. It can feel strange adjusting to a new body. But all that new weight gain can be perfectly fine as long as body fat, muscle, and bone are in the right proportion. Instead, they use the body mass index, or BMI. BMI is a formula that doctors use to estimate how much body fat a person has based on his or her weight and height. This number is then plotted on a BMI chart, which helps tell a person whether he or she is in the underweight, healthy weight, overweight, or obese range. The growth charts have lines for "percentiles. The eight lines on the BMI growth charts show the 5th, 10th, 25th, 50th, 75th, 85th, 90th, and 95th percentiles. The 50th percentile line is the average BMI of the teens who were measured to make the chart. When your BMI is plotted on the chart, the doctor can see how you compare with other people the same age and gender as you. Based on where your number is on the chart, a doctor will decide if your BMI is in the underweight, normal weight, overweight, or range. Anyone who falls between the 5th percentile and the 85th percentile is in the healthy weight range. If someone is at or above the 85th percentile line on the chart but less than the 95th percentile, that person may be overweight. A BMI measurement over the 95th percentile line on the chart puts someone in the obese range. A doctor can use BMI results from past years to track whether you may be at risk for becoming overweight. Spotting this risk early on can be helpful because the person can then make changes in diet and exercise to help head off a weight problem. People can have a high BMI because they have a large frame or a lot of muscle like a bodybuilder or athlete instead of excess fat. Likewise, a small person with a small frame might have a normal BMI but could still have too much body fat. These are other good reasons to talk about your BMI with your doctor. Your doctor has measured your height and weight and has plotted your BMI over time. If your doctor is concerned about your height, weight, or BMI, he or she may ask questions about your health, physical activity, and eating habits. The doctor can then put all this information together to decide whether you might have a weight or growth problem. Most teens who weigh less than other people their age are just fine. You might be going through puberty on a different schedule than some of your peers, and your body may be growing and changing at a different rate. In a few cases, teens can be underweight because of a health problem that needs treatment. See a doctor if you notice any of these things: You feel tired or ill a lot. You have a cough, stomachache, diarrhea, or other problems that have lasted for more than a week or two. Some people are underweight because of eating disorders, like anorexia or bulimia, that they need to get help for. Getting Into Your Genes Heredity plays a role in body shape and what a person weighs. People from different races, ethnic groups, and nationalities tend to have different body fat distribution meaning they have fat in different parts of their bodies or body composition their amounts of bone and muscle versus fat. But genes are not destiny. Unhealthy eating habits can be passed down, too. The good news is these habits can be changed for the better. It can be tough dealing with the physical changes your body goes through during puberty.
