To appreciate the above diagram, let's first understand - What is a Software Build? If you are developing a simple computer program which consists of only one source code file, you merely need to compile and link this one file, to produce an executable file. This process is very simple. Usually this is not the case. A typical Software Project consists of hundreds or even thousands of source code files. Creating an executable program from these source files is a complicated and time-consuming task. You need to use "build" software to create an executable program and the process is called " Software Build" What is Smoke Testing? Smoke Testing is a kind of Software Testing performed after software build to ascertain that the critical functionalities of the program is working fine. It is executed "before" any detailed functional or regression tests are executed on the software build. The purpose is to reject a badly broken application, so that the QA team does not waste time installing and testing the software application. In Smoke Testing, the test cases chosen cover the most important functionality or component of the system. The objective is not to perform exhaustive testing, but to verify that the critical functionalities of the system is working fine. For Example a typical smoke test would be - Verify that the application launches successfully, Check that the GUI is responsive What is Sanity Testing? Sanity testing is a kind of Software Testing performed after receiving a software build, with minor changes in code, or functionality, to ascertain that the bugs have been fixed and no further issues are introduced due to these changes. The goal is to determine that the proposed functionality works roughly as expected. If sanity test fails, the build is rejected to save the time and costs involved in a more rigorous testing. The objective is "not" to verify thoroughly the new functionality, but to determine that the developer has applied some rationality sanity while producing the software. Both sanity tests and smoke tests are ways to avoid wasting time and effort by quickly determining whether an application is too flawed to merit any rigorous testing. Sanity Testing is also called tester acceptance testing. Smoke testing performed on a particular build is also known as a build verification test. One of the best industry practice is to conduct a Daily build and smoke test in software projects. Both smoke and sanity tests can be executed manually or using an automation tool. When automated tools are used, the tests are often initiated by the same process that generates the build itself. As per the needs of testing, you may have to execute both Sanity and Smoke Tests on the software build. In such cases, you will first execute Smoke tests and then go ahead with Sanity Testing. In industry, test cases for Sanity Testing are commonly combined with that for smoke tests, to speed up test execution. The Video will load in some time. So naturally, when gifted scientist Sanity uses her lab skills and energy allowance to create a definitely-illegal-but-impossibly-cute three-headed kitten, she has to show Tallulah. The girls will have to turn Wilnick upside down to find her, but not before causing the whole place to evacuate! Readers will be over the moon for this rollicking space adventure by debut author Molly Brooks I would have liked some back story, which I know is hard to do with the format it is in. The story line was okay, and I think kids that are into science and space will really like this book. I received a copy of this book from NetGalley in exchange for an honest review. Disney-Hyperion Public This book is a graphic novel and a pretty easy read. Molly Brooks Publication Date: Without permission they create a life form that gets loose aboard the ship. I loved the illustrations in this book and how well they went with the story. This book was a wonderful, fun read and I highly recommend it! Excellent visual story telling that works well with the text. Two friends living on a older space station where repairs are a part of life. Scientist Sanity creates a three-headed kitten in the lab without permission and when it escapes all chaos ensues. Tallulah who is apparently in trouble a lot is perfectly happy to help Sanity search the station for the kitten. What they encounter in the bowels of the station is not just the kitten, but trouble. Luckily, Sanity knows what needs to be done to save the This was a wonderful middle grade graphic novel. Luckily, Sanity knows what needs to be done to save the day. Sanity, who is advanced in her understanding of science, and Tallulah, her best friend, who is not quite as in to science, have created a three headed cat, despite the fact that no animals other than humans are allowed on the space station that they live on. Here is the three headed cat, below. The world building is well done. It appears as though This is a fun book. It appears as though this is a first in a series, which will be fun. This will be an excellent series, with miscivious but normal pre-teens, and exasperated parents, and bureaucracy and all the fun things that go into a good science fiction story. Thanks to Netgalley for making this book available for an honest review.

In the initial level testing software is tested for readiness before the detailed testing by QA team. Initial level testing is also called as build acceptance testing. A build is a complied code packaged in a single file called as. The two terms smoke testing and sanity testing are sometimes used interchangeably. Below are the two terms smoke testing and sanity testing explained with examples. It is testing technique which works similar to hardware testing. Suppose if u have any hardware device and you connect to the power and switched on if you get smoke then the test fails. In the same way it is applicable in software to test the basic functionality which is built. If it fails then it is considered as unstable. The primary goal of smoke testing is verify the main application functionalities and to satisfy the product. For example if a software has modules with the login page, main page and gallery. This testing deals whether the user is able to login properly with the valid credentials or is there a facility to create new user whether he can open the main page or gallery by logging in etc. It is done to check whether the system has acquired any new problem or any bugs has left unfixed. It is mostly done after retest that after fixing all bugs in the software. For example your software has five modules Login page, Main Menu page, Form filing page and Feedback page. If any new functionality should be added like there is no new user creation or password reset option in the application. Then the QA team sends the application to development team. The developer team adds functionality to the application and checks the functions of all other pages as retest for any other minor problems which has to be fixed. It is also called as quick regression testing. There is always confusion between sanity testing and smoke testing. Sanity testing is done when the developer or a tester wants to know the quick performance of the product. Smoke testing is done after the software is developed to check the critical functionalities of the software. Try to identify the differences and similarities between smoke testing and sanity testing.

In manual testing test cases are executed manually without any support from tools or scripts. but with automation testing test cases are executed with the assistance of tools scripts and software. Testing is an integral part of any successful software project.
