## Chapter 1 : Volume One Magazine - Eau Claire Culture and Entertainment

*This One's on Me (The Bandy Papers, Vol. 6) by Jack, Donald. Doubleday Canada. Used - Good. Former Library book. Shows some signs of wear, and may have some markings on the inside.*

Every book in the Bandy Papers series contains the word "me" in the title, as do many of the chapter titles, which can also be interpreted as photo captions. The Bandy Papers books are: Three Cheers For Me [1] This small novel was later expanded into the first 3 volumes: Me [1] Stalin vs. Me Bandy was born on July 14, Physically he is described as over 6 feet tall and with a face like a horse. His voice is high pitched and whiney and is said to resemble that of W. Fields , whom he once met. This combination seems to drive most people and many animals he meets to dislike him and as a result he has developed a "stone face" to counter these attacks a defense that often backfires by inciting his enemies to greater levels of malice. His talents, although well disguised, are real and he has certainly been an influential though minor character in history. Bandy was born and raised in Beamington, in the Ottawa Valley in Ontario, where his father was a minister. From his published papers, he seems to have had a difficult time fitting in with his school mates. There is a reference in Me Bandy, You Cissie that he was an invalid for a time during his childhood. Bandy volunteered for the infantry in after being kicked out of medical school and was commissioned as a 2nd lieutenant in the Canadian Army. After spending some time in the trenches, it was decided that the infantry was not entirely suited to his talents and so he was transferred into the Royal Flying Corps , where he stayed on and off for the rest of the war, until being sent to Russia to fight Bolsheviks, where he was captured by Red Russian forces at the Battle of Toulgas on November 11, His military career went from the heights of the Air Board to the lows of fighting in a Bicycle Battalion. After the war and his imprisonment in Russia, Bandy had short but illustrious careers in silent films , rum-running , politics, and airplane design. When several of his careers threatened to land him in prison or worse, Cabinet , Bandy returned to Europe, flying via Iceland, in an attempt to restore his fortunes through the marketing of the Gander, an amphibious aircraft of his design. His plans came to naught when he lost the Gander during the rescue of a downed aviator in the English Channel. He was forced to seek employment as a lowly hospital porter until being sought out by the rescued aviator, who turned out to be the son of an Indian Maharajah. This led to him being knighted, but he seldom used his title. It is mentioned that he flew for the Republicans in the Spanish Civil War , but this is not detailed. The books are noted for their humour and word play, as well as technical and historic accuracy except possibly in India. An Annotated Guide to Novels in Series".

*This One's On Me: Volume VI of The Bandy Papers and millions of other books are available for Amazon Kindle. Learn more Enter your mobile number or email address below and we'll send you a link to download the free Kindle App.*

I was reading a lot of military fiction then, and the cover, here, with biplanes and a promise of comedy and a Canadian perspective on the Great War was more than enough to pull me in. I found *Three Cheers For Me* in a used bookstore, of course, as the books had been out of print for a decade or so when I first got hooked, but I continued to prowl used bookstores across Calgary, searching for further tales of the redoubtable Bandy. I believe Donald Jack is the man who introduced me to the word "redoubtable", actually. Not to mention "obviate", and probably "spifflicated", too. Interesting that Jack -- a Brit who emigrated to Canada after World War II -- should come to write a series with such a dedicatedly Canadian bent on history. Bandy is self-righteous, deceitful, annoyingly smug, and lacks the ability to see himself and his own foolishness clearly. These books deserve a vast audience, inside or outside of Canada. Of course, being Canadian, most Canadians will be suspicious of the idea that a story about Canadians would be entertaining. This attitude does seem to be changing. Slowly, of course, for we Canadians change nothing quickly, but recently the idea that Canadian television might have qualities beyond easing digestion seems less far-fetched. The Bandy Papers might one day be seen as an early salvo in the battle to establish the idea that Canadian stories can be entertaining. Jack might be seen as a visionary who, as early as dared to attempt writing an adventure novel about a Canadian. And succeeded, in point of fact. Bartholomew Bandy of Beamington, Ontario, goes off to fight in World War I, survives the trenches but infuriates his commanding officer so much that he is promoted to the Royal Flying Corps where his life expectancy is only a few weeks, and promptly becomes one of the great aces of the war, simultaneously creating so many enemies among the military and political establishment that his career shifts are measured in hours. Much hilarity ensues, and much savagery as well, for Jack is writing out of a profound anger towards the powerful who sacrificed so many lives for so little gain. As the books proceed, the shells Bandy inhabits in order to manage his internal fury get stripped away and yet the comedy never goes away. He never loses his wry sense of the absurdity of all this fuss and bother, even when he is helpless in his efforts to placate and soothe the worst of the fussers and the botherers. He trades quips with Dorothy Parker and terrorizes William MacKenzie King and is in fact responsible for the collapse of his government in He seduces and is seduced, rejects and is rejected. There is little rhyme or reason to who ends up his allies and who his enemies; by no means is it clear that "sensible" people like him and fools do not. And yet he is deeply charismatic, especially to the reader. This is probably because of his honesty to us. While he is willing to fib outrageously to others, with his readers, Bandy shows a respect for the truth even when it is uncomfortable or unflattering -- and although he often undermines his own efforts at self-deprecation with a mock self-righteousness, Jack always seems to find just the right tone that will let us know that Bandy takes himself no more seriously than he takes anything else in the world. These books were a huge influence on me. Donald Jack died in , at the age of I am immensely grateful to him for his efforts, as they have brought me more joy over the past twenty years than I could have expected from that aging, yellowed volume I first picked up in a Calgary used bookstore.

A reasonably complete listing of my research papers since can be found on DBLP. References with citations can be found on Google Scholar Below are abstracts of some recent papers by me and my co-authors, as well as links to copies of the papers. The papers are organized by research topic. Submitted for publication The aim of this paper is to establish a theory of random variables on domains. The key idea is to use the Cantor tree to prove that each Borel subprobability measure on a Polish space is the push forward of Lebesgue measure by a measurable map by defining an approximating sequence of simple measures each of which can be similarly realized using Scott-continuous maps. The construction also allows a proof that the measurable mappings each realizing measure in a weakly convergent sequence of subprobability measures on a Polish space converge a. Theoretical Computer Science, to appear. This is the first of two papers that examine a construction of a domain of continuous random variables with values in bounded complete domains. In this paper, we investigate the structure of the thin probability measures on the bounded complete domain of finite and infinite words over a finite alphabet. Computation, Logic, Games, and Quantum Foundations. This is the second of two papers that examine a construction of a domain of continuous random variables with values in bounded complete domains first devised by Goubault-Larrecq and Varacca and presented in their LICS paper. In this paper, we apply the results from our first paper on this subject to present a detailed construction of the domain of continuous random variables based on the domain of finite and infinite words over a finite alphabet, and taking values in a bounded complete domain. Our construction generalizes the construction of Goubault-Larrecq and Varacca, who restricted attention to the case of a two-letter alphabet. Our investigation confirms that the monad laws are valid, but it reveals that the Kleisli extension needed to define the monad on BCD, the category of bounded complete domains, is not Scott continuous. We leave as an open problem whether the construction can be rescued to obtain a monad on BCD. Theoretical Computer Science , pp. This is the journal version of the next listing. In this paper we initiate the study of discrete random variables over domains. Our work is inspired by work of Daniele Varacca, who devised indexed valuations as models of probabilistic computation within domain theory. The approach relies on new results about commutative monoids defined on domains that also allow actions of the non-negative reals. Each of these families leads to the construction of a family of discrete random variables over domains, the second of which forms the object level of a continuous endofunctor on the categories RB domains that are retracts of bifinite domains , and on FS domains where the identity map is the directed supremum of deflations finitely separated from the identity. The significance of this last result lies in the fact that there is no known category of continuous domains that is closed under the probabilistic power domain, which forms the standard approach to modeling probabilistic choice over domains. The fact that RB and FS are Cartesian closed and also are closed under a power domain of discrete random variables means we can now model, e. In this paper we explore discrete random variables over domains. We show that these lead to a continuous endofunctor on the categories RB domains that are retracts of bifinite domains , and FS domains where the identity map is the directed supremum of deflations finitely separated from the identity. The significance of this result lies in the fact that there is no known category of continuous domains that is closed under the probabilistic power domain, which forms the standard approach to modeling probabilistic choice over domains. The fact that RB and FS are cartesian closed and also are closed under the discrete random variables power domain means we can now model, e. This paper presents a domain model for a process algebra featuring both probabilistic and nondeterministic choice. The former is modelled using the probabilistic powerdomain of Jones and Plotkin, while the latter is modelled by a geometrically convex variant of the Plotkin powerdomain. The main result is to show that the expected laws

for probability and nondeterminism are sound and complete with respect to the model. We also present an operational semantics for the process algebra, and we show that the domain model is fully abstract with respect to probabilistic bisimilarity. In this paper we describe how to build semantic models that support both nondeterministic choice and probabilistic choice. Several models exist that support both of these constructs, but none that we know of satisfies all the laws one would like. These models are distinguished by the fact that the expected laws for nondeterministic choice and probabilistic choice remain valid. We also describe some potential applications of our model to aspects of security. In our language concurrency is taken as a primitive operator, rather than being defined in terms of parallel composition and nondeterminism. In fact, our language does not support nondeterministic choice. Our treatment of hiding is novel, in that we record the unwinding of recursion, so that divergence is observable. This avoids our having to assume that divergence is catastrophic, as is done in CSP. Still it is possible to regain a more traditional semantics by simply hiding the resources that unwinding recursions use. We present both an SOS-style operational semantics for our language, as well as a denotational model based on resource pomsets, a generalization of the notion of resource trace that was used in the earlier paper. In addition, we show our denotational model is adequate and fully abstract with respect to the behavior function which extracts from the operational semantics only the set of strings of actions a process can execute. This paper for which the first link is an extended abstract presents a simple programming language which uses the concatenation operator of trace theory as its basic operator as opposed to sequential composition, which is more traditional in process algebra. Heretofore, denotational models supporting this operator have proved elusive because the concatenation operator is not monotone. This barrier has been overcome by the work of Diekert and Gastin and the work of Gastin and Teodesiu, which has provided domain-theoretic models for concatenation. In this paper, we utilize the resource traces model of Gastin and Teodesiu as the basis for our denotational model. This allows us to include in our language a restriction operator which restricts processes to a prescribed subset of the resources, and we also include synchronization on channels represented again as subsets of the resource set, as well as process variables and recursion. We give an operational semantics for our language in the traditional SOS style, and we show that the behavior of processes as defined by this semantics is the same as the denotational mapping our denotational semantics defines on the language - i. In the model-checking community, partial order methods are used to reduce the number of paths of computation that need to be checked. This is accomplished by defining an independence relation on transitions in the system under study, and then performing a selective search that produces a representative path to be checked for each set of independent computations. The main result in this paper shows that such independence relations can be realized as the relation on the simple language studied in the previous paper induced by the denotational mapping. This allows one to code up the words of the language accepted by the automaton of the concurrent system that is being model-checked as processes in the language of that paper so that words of the automaton are independent if and only if they are represented by independent processes in the language. The paper presents a domain-theoretic approach to devising models for unbounded nondeterminism. Using local cpos as the basis for modeling unbounded nondeterminism, the results show that there is no analogue for the lower power domain to support unbounded nondeterminism, but that there is a cartesian closed category which includes an analogue to the upper power domain for unbounded nondeterminism, and in which the mappings all have least fixed points. Left open is the question whether there is an analogue for the convex power domain for unbounded nondeterminism; while the claim is made in the paper that no such object exists, the example presented only shows that the "obvious candidate" will not suffice, because it is not a local cpo. This theory then is applied to give a denotational semantics for a dialect of Timed CSP which supports unbounded nondeterminism. For a copy of the paper, send email to me at mwm AT math. This paper shows how an operational model and related adequate and fully abstract denotational model for a base language can be extended to models for the language of closed terms for the language extended to include identifiers and recursion operators. The paper also presents new notions which are called order adequacy and order full abstraction which arise naturally because of the assumptions that the operational

and denotational models both are ordered spaces. This paper starts with a "base language" without identifiers and an operational model and related denotational model which is adequate and fully abstract for the operational model. Then it is shown how to extend the operational and denotational models to ones for an extension of the language which supports recursion through systems of recursive equations so that the extended denotational model again is adequate and fully abstract with respect to the extended operational model. In this paper, we show that any two group structures on the Cantor set have the same Haar measure, and we also should that each Haar measure maps to Lebesgue measure on the unit interval under the canonical mapping from the Cantor set to the unit interval. In this paper, we describe three distinct monoids over domains, each with a commutative analog, the latter of which define bagdomain monoids. Our results were inspired by work by Varacca. We use our constructive approach to show that the laws Varacca lists as characterizing the Hoare indexed valuations are not complete for the construction he gives. Our construction reveals the missing law, and we also indicate how to repair his construction so that the laws he lists do characterize the construction. In this paper we show that under modest conditions, a measurement on a domain  $D$  lifts in a natural way to a measurement on the probabilistic power domain  $V D$ . The paper shows how local cpos those in which only the lower set of a point is a cpo can be used to provide bounded complete models for topological spaces. A construction using the bounded Scott-closed sets is given that provides such a model for any topological space that has a domain-theoretic model. This last means that the space is homeomorphic to the maximal elements of a continuous dcpo which itself is weak at the top  $i$ . For example, the model for Polish spaces devised by Lawson and the formal ball model of Edalat and Heckmann both satisfy this criterion, and so these models can be "converted to" bounded complete local cpo models. This is a revised version of an extended abstract that is drawn from my address at the first ETAPS conference in Lisbon in March. The paper reviews some of the basic aspects of domain theory, and then goes on to describe a number of generalizations that have arisen in response to solving problems with domain-theoretic techniques, but for which domain theory per se did not apply. Appeared in *Topology and Its Applications*. The paper reviews some of the central results about domain theory and its applications to theoretical computer science with an eye toward demonstrating why order theory together with topology --  $i$ . There are some new results in the paper, including a new derivation of the classical power domains and some results about models of the lambda-I calculus. The latter were pointed out to the author by Furio Honsell Udine after the lecture on models of the untyped lambda calculus that was one of the lectures in the series. Jean Goubault-Larrecq pointed out an error in the proof of Proposition 4. In this short note, we correct that proof, and also give a simpler proof that the convex power domain of a coherent domain is again coherent. A continuous lattice is a linear FS-lattice if the identity map is the directed supremum of selfmaps that are finitely separated from the identity. These lattices recently have been used to provide semantic models for linear logic. In this note, we show that a continuous lattice is linear FS if and only if its function space of sup-preserving selfmaps is a Scott-continuous projection of its function space of Scott-continuous selfmaps. Further, we show that a continuous lattice is completely distributive if and only if the function space of sup-preserving self maps is a sup-projection of its function space of Scott-continuous self maps. We also investigate the structure of the space of selfmaps of certain prototypical continuous lattices that fail to be linear FS lattices. The paper examines the role of the duality between the categories of cpos and upper adjoints and cpos and lower adjoints in solving domain equations. It is shown that a number of domain equations can be shown to have a solution simply by applying this duality. It also is shown that the duality theory allows the equations in question to be solved in the simpler setting of partially ordered sets and monotone mappings. Moreover, it is shown that the results also hold in the more general setting of abstract bases and ideal maps, a category introduced in this paper. This paper explores adjunctions between various categories of domains and  $lluf$  subcategories of the category of Scott domains and Scott continuous functions; ie, those subcategories whose objects are all Scott domains, but whose morphisms are more limited. After recasting the Hoare power domain in this setting, two adjunctions using the Smyth power domain are considered. The first is the traditional Smyth power domain functor, while the second uses the

**DOWNLOAD PDF THIS ONES ON ME (THE BANDY PAPERS, VOLUME 6  
(BANDY PAPERS, VOL 6)**

same construct on objects, but varies the morphisms. Finally, a new adjunction is explored which associates to domain its family of Scott-closed subsets. The paper also explores this construction as an information system. Hofmann pdf version This paper shows that there are no non-degenerate compact Hausdorff models for the untyped lambda calculus, thus limiting the possible models within the category of Hausdorff  $k$ -spaces. Using a connection that models machines on the one hand, and the data they manipulate on the other, testing is used to capture the interactions of each with the objects on the other side: While this approach is based on duality theories that now are common in semantics, it accomplishes much more than simply moving from one side of the duality to the other; it faithfully represents the interactions that embody what is happening as the computation proceeds. Our basic philosophy is that tests can be used as a basis for modeling interactions, as well as processes and the data on which they operate. In more abstract terms, tests can be viewed as formulas of process logics, and testing semantics connects processes and process logics, and assigns computational meanings to both. Labelled Markov processes LMPs are probabilistic automata with a measurable state space.
